

x: Hamming distance h between the two variants of a pair, integer ticks. y: $V(h)/V(\infty)$, log scale. The number beside the open $h=1$ circle is $V(1)/V(\infty)$, the statistic the C1 clause is decided on; the title carries T04's C1 verdict (INC = INCONCLUSIVE, REF = REFUTED). Error bars are ± 1 SE from N_h (T05.V_h_se, put on the ratio scale with the table's own $V(\infty)$ from its h ="random" row); they are bars and not a band, because in F1-F7 a shaded region only ever means a real null envelope or a frozen decision region. The N1 and N2 ribbons spec Sec.6 asks for are NOT drawn: T05.V_h_N1_lo / V_h _N1_hi / V_h _N2_mean carry 0 finite values in this run, and a band that is not a real 5th-95th null envelope is forbidden. The peak marked is the first interior local maximum resolved beyond the tabulated SEs (rise and fall each $> 2 \times$ the pooled SE of the compared points); where the curve is still rising at $h_{\max}$ no peak is marked, because no fall has been observed. Bottom row = CONTROL tier, not data points (outlined): Z-LL1 and Z-LL2 sit ABOVE $V(\infty)$ at $h=1$, the pre-declared negative result, on the same axes as the positive ones.
