

whole-assay ranking says nothing about the cliff edges

$\tau = 3$: the C2 window's lower edge and the C3-N cliff definition. Spec Sec.6 does not name a τ and T12 carries 2, 3, 4, 5, 6, 8; the same figure at another τ is one argument away. Error bars in (a) are the tabulated 95% CI of PSA on cliff edges (T12.PSA_lo95 / PSA_hi95). Spec Sec.6 asks for "AUPSA on cliff vs non-cliff edges": T12's AUPSA is ONE number per (assay, model) and is not split by cliff status (it is also constant in τ), so the split drawn in T12's own PSA_cliff vs PSA_noncliff and AUPSA is marked separately as a diamond. T12's verdict_blindspot and verdict_practical_emptiness columns are empty, so the three horizontal calls are the frozen THRESH lines and are NOT read from the table.
